NOISE BARRIER SCOPE SUMMARY REPORT

1. INTRODUCTION

A. Proposal and Limits

Construct ten noise barriers on both sides of Route 580 freeway from KP53.9 to 55.7, between Estudillo Avenue and 141st Avenue. This NBSSR replace the Project Report.

B. Deficiencies & Justification

Section 215.5 of the Streets and Highways Code requires Caltrans to develop and implement a system of priorities for the need of installation of noise barriers along freeways in the California freeway and expressway system. The highest consideration shall be given to residential areas, which were developed prior to the opening of the freeway or if alterations made to the freeway since its original opening, caused a 3dBA increase in ambient noise levels.

This project meets the above requirements and was originally prioritized on the State HB311 Candidate project list.

C. Project Category

Since this project will be of minimal economic, social, or environmental significance, it will be Categorically Exempt under CEQA, and be a Category 5 project.

2. BACKGROUND

A. Funding Source:

This project will be funded by the Ala Co CMA, not the HB311 program.

(1) Is project in STIP? No.

This project will be programmed in the STIP cycle 2003 by the Alameda Congestion Management Agency (ACMA)

(2) Is project being advanced by local agency with costs to be paid back by State ? No.

The California Department of Transportation (Caltrans) had a Community Noise Abatement Program (HB311) to prioritize and ultimately construct soundwalls along existing freeways under Section 215.5 of the California Streets and Highways Code. The program has undergone sweeping change under SB45, which fundamentally change the way soundwall projects are programmed and administered. SB45 repealed the separate programming element for soundwalls, and shifted programming authority to local Regional Transportation Planning Authorities (RTPAs). RTPAs, at their option, can fund soundwall projects in their RTIP. They may also set different qualifying criteria or programming priorities. Alameda County Congestion Management Agency (ACMA) submitted project nomination Fact Sheet for the programming of STIP funds for the entire ten walls.

B. Public Involvement

(1) Community support and/or opposition:

This location has received many complaints concerning excessive freeway traffic noise impacting the residential units.

(2) Actual or proposed community contact about proposed noise barrier and aesthetics:

The public meeting will be held after NBSSR, Environmental document, Exhibits are ready and set up with the help of ACCMA and the City of San Leandro.

- (3) Commitments to Local Agencies: None
- (4) Unresolved issues: None

C. Project Priority

On Statewide Priority List: Not Applicable

3. DESIGN INFORMATION

A. Existing Facility

(1) The existing facility is an eight-lane freeway, designated as a scenic route. The topography includes flat and rolling grades with dense shubbery growth and tall native trees along the freeway.

B.

(1) Noise Barrier:

Ten locations were chosen for the noise barriers. The attached layouts and typical cross sections provide more information regarding the

04 - ALA - 580, KP53,9/55.7 (PM33.5/34.6) RU4248 - 126200

heights, length, and limits of the noise barriers. See Attachments B and F. Within the proposed project limits, existing trees and other vegetation may need to be removed, and light posts that need to be relocated. No other unusual features are noted.

Approximately 75 and 45 meter bridge barrier railings shall be removed and retrofitted with new concrete barriers with soundwall on the top for the San Leandro Creek bridge and Estudillo Avenue Undercrossing respectively. A 120 meter long Type 1 cantilever retaining wall must be retrofitted with a concrete barrier and sound wall.

(2) Right of Way and Fencing

Construction easements will be needed for portions of the proposed noise barriers along the State's Right of Way. About 1000 meter of chain link fence and 400 plus meter Metal Beam Guard Railing will need to be removed.

(3) Traffic Data

a. Current Year: 2000

ADT: 126,000 % Trucks: 1.20%

b. Design Year: 2020

ADT: 171,000 DHV: 13,680

Noise Study Completed? Yes. Date: 01/05/01

Noise Report Prepared? Yes. Date: 01/05/01

Datum of Noise Barrier Height Basis: Both ETW and R/W Line

4. PROPOSAL

A. Description:

It is proposed to build soundwalls on Route I-580 in San Leandro, from Estudillo Avenue to 145th Avenue to mitigate the effects of excess traffic noise on residents adjacent to the freeway. Ten locations were chosen on both sides of the freeway. No widening is proposed in this project. The shoulder will be extended from 0.7 m to 0.9 m along those segments of the noise barrier that are located on shoulder. This shoulder work is necessary to establish between 3.353 and 3.734 m of horizontal clearance. The soundwalls along the R/W line will be more than 4.5 m from the edge of the traveled way. A safety shape concrete barrier is required for all noise barrier within 4.5 m of the edge of traveled way (see Highway Design Manual index 1102.2), hence noise barrier segments along the edge of shoulder will be placed on safety shape concrete barrier. There will be structure retrofit work required on both the San Leandro Creek bridge, Estudillo Avenue under crossing bridge, and retaining wall "M". See Attachment C.

B. VA Study:

All soundwalls will be located either near the edge of shoulder in embankment fill areas or at the State's Right-of-way in cut areas. The choice of materials will be based on aesthetic considerations, community acceptance and cost.

C. Acceptable noise barrier materials for proposed project:

The possible alternative designs included in final project, as per HDM Index 1102.7 are shown below:

- i. Masonry Block wall
- ii. Concrete Panel wall

The final selection, however, will be made during the PS&E stage.

Soundwalls on the San Leandro Creek bridge, Estudillo Avenue UC bridge and Retaining wall "M" will be designed by the Division of Structure.

D. Noise Study Recommendation(s):

Wall	Description	Length	Height	Direction(EB,WB)	No. of
No.	-	(m)	(m)	and Location (R/W line, shoulder)	homes
I	140th/143rd Ave	93	3.7	EB shoulder	11
2	On Velarde bet 140 th /Lopez	308	3.7	EB R/W line	5
7	On Kingsway bet Russ/143rd	306	3.7	EB shoulder	3
8	On Grand bet Kenton/Emerald	521	3.7	EB R/W line	23
10	On EB 580 bet Maud/Dolores	181	3.0	EB shoulder	22
3	On Benedict bet Scenic View/Estudillo	528	3.0	WB shoulder	18
4	On Benedict bet Grand/Hillside	121	3.7	WB R/W line	5
5	On Benedict bet Scenic View/Hillside	195	3.7	WB R/W line	10
6	On Benedict bet Scenic View/Hillside	213	4.9	WB R/W line	10
9	On Benedict bet Admore/Grand	178	3.0	WB R/W line	6

E. Noise Barrier Foundation:

(1) Locations where soil or other conditions would require nonstandard foundations:

At this stage we do not know if non-standard foundations will be required, but this will be investigated during the PS&E stage. In case soil or other conditions require non-standard foundations, special design will be requested from the Division of Structures during the PS&E stage.

(2) Non-standard foundation locations (including: Wall Number, Limits, and Foundation Type):

San Leandro creek bridge No. 33-07 (75 meter, spread footing on steel piles)

Estudillo Avenue UC bridge No. 33-332 (41.148 meter, 2 curtain wall abutments & 2 bents)

Retaining Wall "M" (120 meter type 1 cantilever, spread footing)

Division of Structures Recommendation:

Bridge Site data was sent to Structure Design for Advance Planning Study. Division of Structures will design these non-standard foundation incorporated with the existing foundation.

F. Design Details:

The design details for the project will be provided at the PS&E stage.

Pavement/shoulder rehabilitation or reconstruction: Pavement/shoulder

rehabilitation or reconstruction may be required. The extent of work will be small. Refer to the preliminary cost estimate.

Drainage: Drainage work will be required

Signs: No permanent signs are required for this project.

Lighting: Along the edge of shoulder, existing lighting poles need to be modified or relocated during construction of soundwall.

Utility Relocation: ROW is in the process of contacting utility companies for the utility verification, but we do not expect any relocation necessary.

Structure Work: Replace existing bridge railing with Type 736 Safety shape concrete barrier and retrofit top portion of retaining wall M.

Highway Planting: Some small trees may need to be removed for construction purpose and any replacement or mitigation will be determined by Landscape during PS&E.

Planting/Irrigation Modification: The extent of the planting/irrigation modifications will be determined after the exact location of the noise barriers has been established.

Ramp Metering: No ramp metering will be done as part of this project.

G. Nonstandard design features: Caltrans standard noise barrier design is utilized.

Mandatory Design Requirements : All design features meet the requirement of Mandatory standards.

Date of Fact Sheet approval: Not Applicable.

Advisory Design Requirements: Not Applicable.

H. Cost Estimate:

Construction \$ 4,469,217

Right of Way \$86,500

Total \$4,555,717

See Attachment 3 for Preliminary Cost Estimates.

I. Analysis of Proposal

(1) Cost effectiveness (See HDM Index 1104.6):

This project meets the cost effectiveness criterion of \$45,000 per residence established by the Alameda County CMA.

Estimated cost of project

\$4,555,717

Residential uints protected

113

Cost per unit

\$40,316

(2) Noise Reduction

5 dBA reduction is the minimum noise level of attenuation.

• The projected future noise level is estimated to be in the range of 77 to 83 dBA. The proposed noise barrier facilities are expected to lower noise levels to an average of 68 dBA. All noise levels in this report use descriptor Leq (h).

DIR	Wall No	Height(m)	Future(No Wall)	Future(With Wall)	Average Attenuation(dBA)
EB	1	3.7	80	66	14
EB	2	3.7	81	68	13
EB	7	3.7	81	70	11
EB	8	3.7	80	66	14
EB	10	3.0	82	71	12
WB	3	3.0	77	68	9
WB	4	3.7	78	67	10
WB	5	3.7	78	68	10
WB	6	4.9	81	69	12
WB	9	3.0	79	70	9

Level of Service "C" with the following assumptions were made:

Vehicles/hour/lane =2,000

Speed =105 Kph

See table C-1, C-2, D-1, & D-2 in Traffic Noise Impact Report (Attachment E) for detailed breakdown of the existing and future noise conditions determined during model calibration counts. See Exhibit E for traffic assumptions (VPH) for the TNM noise computer model.

• Intercept of line of sight to Truck Exhaust Stack:

After minimum noise barrier heights were determined through noise modeling, further height adjustments were made to intercept the line of sight between a truck stack assumed to be 11.5 feet above ground and a receptor assumed to be 5 feet above ground.

J. Funding and Staffing

(2) Proposed Budgetary Description:

04-ALA-580 KP 53.9/55.7 (PM 33.5/34.6) In Alameda County, in the City of San Leandro, on State Route 580 eastbound and westbound from Estudillo Avenue to 141st Avenue, construct soundwalls.

5. OTHER CONSIDERATIONS

A. System Planning

- Route Concept Report for project limits:
 Route 580, within the project limits, is an eight lane freeway with 3 meter inside and outside shoulders and divided by concrete barrier. Due to increased traffic volumes, it is essential to mitigate the effects of higher noise levels through the construction of noise barriers at the chosen locations.
- Other proposed projects within this project's limits:

There is no proposal to increase capacity via lane addition projects in the near future.

B. Hazardous Wastes:

In the event that demolition work involves major structures, asbestos could present an issue of concern. Aerially deposited lead (ADL) has been found to be emitted from automobile exhaust and are deposited along the unpaved shoulder areas. There are various requirements that must be met when handling/managing materials with regulated levels of lead: proper testing of materials to be disturbed by construction work activities must be performed following regulation from the Department of Toxic Substances Control (DTSC). The Environmental Engineering unit will test for ADL once the Project Engineer sends the request with appropriate layouts and cross-sections.

Initial Site Assessment: ISA was completed at November 22, 2000.

C. Traffic Control

• Transportation Management Plan for this project is not required.

• Prolonged temporary ramp closures:

Prolonged temporary ramp closures are not anticipated, however, temporary K rail will be used along the shoulder of freeway and bridges, when soundwalls are constructed along shoulder.

• Lane/Ramp Closure Plan (e.g., hours of allowed work):

Most likely, there will not be any lane/ramp closures during normal day-time traffic peak hours. Local street and bridge decks may be restriped to gain construction working space along retaining wall "M" and bridges.

D. Wetlands/Floodplain:

This project is not located in a wetland or floodplain area. Therefore, an evaluation of the effects of the noise barriers on the floodplain, in accordance with Topic 804 of the HDM, has not been performed.

E. Following permits may be required:

Agency	Yes / No	Date Contacted	Results
Fish & Game	no		
Corp. of Engineers	no		
Coastal Commission	no		
BCDC (District 4)	no	•	
Local flood control district	no	· · · · · · · · · · · · · · · · · · ·	

F. Railroad(s) or Utility involvement:

There is no Railroad involvement. However, utility verification will be done after contacting utility companies through Caltrans right of way utility agents during PS&E stage.

Date: 2/1/2001

ACCMA Transportation Engineer:

Matthew Todd

Date: 2/7/2001

Type of Federal Involvement

Federal Funding may be involved in this project.

7. ENVIRONMENTAL STATUS

The Office of Environmental Planning will conduct a preliminary review of the project. Based upon the existing information, the project will require the completion of a Categorical Exemption under Class 1 pursuant to the California Environmental Quality Act and a Categorical Exclusion pursuant to the National Environmental Policy Act. This determination is contingent upon the existing project description. In addition, some conditions will have to be satisfied such as the testing of aerially deposited lead, and specifications for the protection of water resources.

The final project design is required to take into consideration the potential visual impact of the proposed sound wall, the existence of trees at the site, and the impact of potential lane closures on traffic circulation. Measures in the project design may need to be included to ensure that these issues do not have the potential to significantly affect the environment.

8. RIGHT-OF-WAY CERTIFICATION

"I have reviewed the right-of-way information contained in this Noise Barrier Scope Summary Report and the Right of Way Data Sheet attached hereto, and find the data to be complete, current, and accurate."

CATEGORICAL EXEMPTION/EXCLUSION DETERMINATION

PROJECT DESCRIPTION

The project consists of the construction of 10 to 16 foot high soundwalls on both sides of Route 580 between postmiles 33.5 and 34.6 from 141st Street to Estudillo Avenue in the City of San Leandro, County of Alameda. All work will take place within the existing right-of-way.

ENVIRONMENTAL SETTING

Urban

DETERMINATION

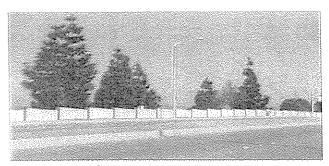

This project has been identified as a Class 1 Categorical Exemption under the Caltrans Environmental Regulations on the basis of a determination that the project, by its nature, clearly meets the criteria for exemption.

It is recommended that this project be determined to be a Categorical Exclusion in accordance with 23 CFR 771.

Introduction

Purpose of Noise Report

The purpose of this report is to reevaluate traffic noise impacts in the study area at the request of the Alameda County Congestion Management Agency (ACCMA). As a result of the implementation of a new noise policy by the Alameda County Congestion Management Agency (ACCMA). The programming of STIP funds to soundwall projects in Alameda County, previously guided by the Caltrans Community Noise Abatement Program (HB311), is now performed by the ACCMA, and the transfer of the Caltrans Community Noise Abatement Program (HB311) in Alameda County over to the ACCMA. The original project scope identified 6 sound walls to be built as part of the Caltrans HB311 program in the December 1992 Noise Barrier Scope Summary Report (NBSSR). This will serve as the formal Technical Noise Impact Report needed to accompany the updated NBSSR for the project.

Project Description

This project proposes the construction of 4 sound walls on eastbound Route 580 and 6 on westbound Route 580 from 141st Street to Estudillo Avenue in the City of San Leandro, Alameda County.

Land Use and Terrain

The northern and southern portions of route 580 corridor within these project limits consist primarily of residential subdivisions with relatively flat grades and rolling terrain. Both sides of route 580 are lined with thick, dense shrubs and short trees. The existing residential development next to the highway is relatively old and tightly spaced along both directions of route 580. The homes along westbound 580 are largely on top of the slope, whereas the ones on the eastern edge are at the bottom. Most of these homes are single residential, except for a two-story apartment complex (Redwood Grove) on Grand/Delores. There is also a school (Fairmont Elementary) in the southern portion of this project and a hospital (Vencor Hospital) on the eastern side.

Traffic Noise Impacts

Traffic noise impacts occur, when future predicted noise levels increase by 12 decibels as the result of the project or approach the noise abatement criteria (NAC) of 67 dBA, Leq (h) for activity category 'B' as defined in Table 1- 23 CFR, 772 (FHWA). The term 'approach' is defined by Caltrans as one dBA below the criterion. For example, a site with future predicted noise levels of 66 dBA, Leq (h) would qualify for consideration of noise abatement. Although the project will increase noise levels 1-2 dBA at nearby residences, a change of three dBA has been found barely perceptible by the healthy, human ear. However, future predicted noise levels immediately adjacent to the freeway will approach or exceed 67 dBA, Leq(h) at 16 sites and noise abatement in the form of noise barriers has therefore been considered.

For the purpose of this report, activity category 'B' as described in Table 1 – 23 CFR, 772 (FHWA) is used to determine traffic noise impacts and abatement. The Noise Abatement

Criteria (NAC) for Category 'B' is 67 dBA, Leq (h) and includes picnic areas, recreation areas, playgrounds, active sport areas, residences, motels, hotels, schools, churches, libraries, and hospitals. Table 1-23 CFR, 772 (FHWA) is included in the Appendix.

Existing and Future Traffic

Route 580 is a well traveled 8 -lane interstate freeway, with commuting direction going westbound in the morning and eastbound in the evening. Based on the 1999 traffic data, approximately 12, 000 vehicles per hour (VPH) traverse this section of the project during the peak commute hours: 8AM to 9AM in the morning and 5PM to 6PM in the evening.

There is no proposal to increase capacity via lane addition project in the near future, however, projected volume increase in the AM and PM peak traffic will occur in 2010 with the built option of the I-238 highway project. The potential increase is from Caltrans traffic projection study for the 238/580 project:

	AM Pe	ak (VPH)			PM	Peak (VPI	1)	
Scenario	WB	Change	EB	Change	WB	Change	EB	Change
With 238 built	7100		6200		6300		7300	
		+200		+200		+100		· ÷300
No 238 built	6900		5900	ļ	6200		7000	
		+300		+500		+300		+100
2000 Forecast	6600		5400		5900		7100	
TNM Use	7200		7200		7200		7200	

Source: Traffic Forecasting

Ramp volumes are taken from 1999 Caltrans Ramp Volumes data and converted to hourly count for modeling purpose (see Exhibit E).

There is a truck ban in effect, prohibiting any vehicle over a gross weight of 9000 pounds from being operated on the roadway segment between Grand Ave. in the City of Oakland and the city limits of San Leandro. However, trucks over 9000 pounds still traverse this segment of the interstate as periodic, random truck counts reveal. This is taken into consideration in the TNM model, in addition to using traffic forecasting data. Which truck volume to use for modeling is based on the selection of the volume of medium and heavy trucks that correspond to a noisiest hour of the day (in this case 7:00 AM to 8:00 AM and 9:00AM to 10:00AM in the morning for both directions, and 6PM to 7 PM in the evening. – (see Exhibit G). The noisiest hour of the day tends to occur right before or after the commute hours. This is the basis for the selection of truck volume as indicated in the accompanying table:

EASTBOUND (VPH)				WESTBOUND (VPH)					
HOUR	2AX	3AX	4AX	5AX+	HOUR	2AX	3AX	4AX	5AX+
8-9	39	1	2	11	8-9	62	7	1	17
9-10	42	0	1	9	9-10	88	4	2	23

TNM Use	39	1	2	11	TNM Use	88	4	2	23

Source: Caltrans Highway Inventory

Traffic parameters for modeling are summarized in Exhibit E.

Existing Noise Levels

Existing noise levels were determined through field measurements and adjusted upward to reflect the noisiest hour of the day. Measurements where conducted at exterior areas such as yards or frontages of residences facing the freeway. Preliminary noise readings and readings used for model calibration are summarized in the (see Table B). All noise readings use the descriptor Leq (h).

Future Predicted Noise Levels

Future predicted noise levels with and without noise abatement were calculated through computer modeling. Input parameters consisted of hourly traffic volumes (both directions). Based on either an actual traffic projection study or field observations and trends on major Bay Area freeways, or a combination of both (as discussed in the previous section), a speed of 105 km/hr (65 mph) and an hourly volume of Level of Service C (2000 vehicles per hour per lane), a combination of which includes the following vehicle classifications:

- Passenger vehicles
- Medium trucks (2 axles or less)
- Heavy trucks (3 axles or more)
- Buses
- Motorcycles

were used in all modeling scenarios to predict the future noisiest hour of the day. For local streets, posted speed limits and 1,500 vehicles per lane per hour were applied. When feasible, field readings were compared with computed values for model validation. Existing and future noise levels, barrier dimensions, noise attenuation and other details are shown for all receptors (see Table C-1, C-2, D-1, and D-3)

Noise Abatement Considered

Noise abatement in the form of noise barriers has been considered at locations where future predicted noise levels approach or exceed the noise abatement criteria of 67 dBA, Leq (h) for residential areas. Where feasible, the barrier should break the line of sight between a receptor 1.5 meters (5') above ground and a truck stack, assumed to be 3.5 meters (11.5') above the

pavement (see Exhibit F) Minimum height of noise barriers is 1.8 meters (6'); maximum height at the edge of shoulder is 4.3 meters (14') and 4.9 meters (16') at the R/W line.

The views (opinions) of residents directly impacted by the noise barrier under consideration shall be a major factor in noise abatement determination. An impacted resident is defined as any residence receiving a noise reduction of at least five (5) decibels. More than 50% of impacted residents must support the proposed noise barrier construction. Should controversy arise, Caltrans may elect to request the local governing body to mediate and if necessary, submit an approved resolution to the State, whether or not to proceed with construction of the noise barrier(s).

Westbound Direction:

Between Admore Drive and Grand Avenue (Wall # 9)

3.0m x 178m (10' x 584') at R/W line and hinge point (top of slope). The homes are located above the freeway and are directly exposed to traffic, thereby got over 68 dBA. (see Exhibit B & D)

On Benedict Drive between Grand/Hillside (Wall # 3,4,5, and 6)

3.0m to 4.9m (10' to 16') in height and 1057m (3468') in length. This is basically a continuous wall but varies in height to break the truck stack line of sight. The homes are located on top of slope. (see Exhibit B & D)

Eastbound Direction:

On EB 580 between Maud/Dolores Avenues (Wall # 10)

3.7m x 222m (10' x 728') at ES. The receptor is a two-story, 48 unit apartment complex (Redwood Grove), with 11 top and 11 bottom units facing the highway (see Exhibit B & D).

On Grand Avenue between Kenyon/Emerald Avenues (Wall # 8)

3.7m x 521m (12' x 1710') between R/W line and ES. The homes here are below the highway. Receptor # 92, 93, 94, and 95 face route 580 at an angle, thus stopping wall # 8 at Grand Avenue overcrossing will not provide the necessary 5 dBA abatement. Due to the slanted position of these homes, it is recommended that wall # 8 be extended and join wall # 2 to provide the necessary minimum attenuation. Additionally, leaving a gap between wall # 2 and # 8, 600' long is visually intrusive and not a good design practice. The nearby Church of Assumption will get noise abatement as well. (see Exhibit B & D)

On EB 580 between Lopez Drive and Russ Avenue (Wall # 1, 2, and 7)

3.7m (12') in height and 707m (2320') in length. This is basically a continuous wall but varies in location of placement: Wall # 2 will run along the R/W line and Wall # 1 and 7 at the ES. The homes here are relatively lower than the adjacent highway. (see Exhibit D)

Noise Abatement Not Considered

Noise abatement was not considered for locations outside of the original project scope limits and commercial areas.

At some locations, receptors do not qualify for noise abatement based on their existing noise levels. If readings do not approach 67dBA, after adjustments are made for local street and peak traffic noise, no further investigation is warranted.

Westbound Direction:

Sherry to Gabriel Avenue

Measured noise levels adjacent to the freeway ranged from 60 to 63 dBA, Leq (h). These noise levels are below the NAC of 67 dBA, Leq (h) and therefore no noise abatement is required.

Eastbound Direction:

150th to Russ Avenue

Existing noise levels are 62 dBA, Leq(h), below the NAC of 67 dBA and therefore are not eligible for abatement.

Delores Avenue to Collier Drive

This area is largely commercial and is therefore not considered for noise abatement.

Standard Noise Policy and Technical Guidelines

STIP Reform, SB45

The California Department of Transportation (Caltrans) had a Community Noise Abatement Program (HB311) to prioritize and ultimately construct soundwalls along existing freeways under Section 215.5 of the California Streets and Highways Code. The program has undergone sweeping change under SB45, which fundamentally changes the way soundwall projects are programmed and administered. SB45 repealed the separate programming element for soundwalls, and shifted programming authority to local Regional Transportation Planning Authorities (RTPAs). RTPAs, at their option, can fund soundwall projects in their RTIP. They may also set different qualifying criteria or programming priorities.

Existing Noise Levels

Existing noise levels were determined through field measurements and adjusted upward to reflect the noisiest hour of the day. Where noise levels were found to be at or below 62 dBA, no further studies were conducted as outlined in the TNAP. Measurements where conducted at exterior areas such as yards or frontages of residences facing the freeway. Preliminary noise readings and readings used for model calibration are summarized in **Table B.** All noise readings use the descriptor Leq (h). An exhibit depicting common indoor and outdoor noise levels and another exhibit demonstrating relative noise levels can be found in the Appendix as well. All noise values use the descriptor Leq (h).

Future Predicted Noise Levels

Future predicted noise levels with and without noise abatement were calculated through computer modeling. Input parameters consist of hourly traffic volumes including automobiles, medium and heavy-duty trucks, buses and motorcycles. Based on field observations and trends on Bay Area freeways, a speed of 105 km/hr (65 mph) and an hourly volume of 1800 passenger vehicles per lane per hour (in both directions) as well as projected medium and heavy trucks were used in all modeling scenarios to represent the noisiest hour of the day. Modeling considered traffic speeds, roadway grade, terrain configuration, type of groundcover, vegetation, natural and man-made shielding as well as existing noise barriers. When feasible, field readings were compared with computed values for model validation.

Federal Highway Administration's (FHWA) Traffic Noise Model (TNM) Version 1.0b was approved March 1998 for highway traffic noise prediction and analysis. TNM computes highway traffic noise at nearby receivers and aids in the design of highway noise barriers. As sources of noise, it includes 1994-95 noise emission levels for automobiles, medium trucks, heavy trucks, buses and motorcycles. Noise emission levels consist of A-weighted sound levels. In addition, TNM includes full-throttle noise emission levels for vehicles on upgrades and vehicles accelerating away from traffic-control devices such as stop signs, toll booths, traffic signals and on-ramps. TNM combines these full-throttle emission levels with its internal speed computations to account for the full effect (noise emissions plus speed) of roadway grades and traffic-control devices.

Construction Noise

Noise levels from construction activities will be higher at times than currently existing noise levels. Incorporating the following measures in the plans and specifications can minimize these temporary impacts:

- The consideration of constructing noise barriers as first items of work, where feasible.
- Use of stock piled dirt as earthen berms to attenuate the impact of construction activities.
- Avoid construction activities during nighttime and week-ends, when possible.
- Establishment of a field office to handle noise complaints and keep the community informed of upcoming especially noisy construction activities.
- The enforcement of Section 7-1.01I, "Sound Control Requirements" of the Standard Specifications.

Instrumentation

Noise measurement is performed using Metrosonic, Inc Model 3100 sound level meter, set for various time intervals and sampling speeds. The frequency weighting network applied for normal transportation noise sampling is A-scale. Field calibration using a Metrosonic Acoustical Calibrator, CL-304, is performed before each measurement.

The Metrosonic Inc. Model 3100 logger's specifications satisfy the American National Institue of Standards (ANSI) s1.4-1983 and s1.4N-1985 for type 2 meter. A calibration and certification of Model CL-304 calibrator is done every two years by Odin Metrology, Inc. of Thousand Oaks, CA.

Appendix

Existing Noise Environment

Existing noise levels were recorded within the project limits through short-term measurements. A 24-hour measurement was conducted in each direction of route 580 to determine the noisiest hour of the day and to develop a noise profile for that direction (see Exhibit G). The short-term measurements were then adjusted upward, where appropriate, to reflect the noisiest hour of the day throughout the project limits.

A-Weighting, Noise Levels

In general, the human ear is most sensitive to sounds between 1,000 Hz to 5,000 Hz and perceives higher and lower frequency sounds of the same magnitude with less intensity. In order to approximate the frequency response of the human ear, a series of sound pressure level adjustments is usually applied to the sound measured by a sound level meter. The adjustments, or weighting network, are frequency dependent.

The A-scale approximates the frequency response of the average young ear when listening to most ordinary everyday sounds. When people make relative judgements of the loudness or annoyance of a sound, their judgement correlate well with the A-scale sound levels of those sounds. For highway traffic noise, only the A-Scale is used. Other scales are the B-Scale, C-Scale and D-Scale). The A-weighted scale is used worldwide to address environmental noise and is incorporated in virtually all environmental noise descriptors and standards.

Wavelengths serve to determine the effectiveness of noise barriers. Low frequency noise, with its long wavelengths, passes easily around and over a noise barrier with little loss in intensity. For example, a 16 Hz noise with a wavelength of 70 feet (21m) will tend to pass right over a 5 meter (16') high noise barrier. Fortunately, A-weighted traffic noise tends to dominate in the 250 to 2000 Hz range with wavelengths in order of 0.6 to 4.5 ft (0.2 to 1.4m). Noise barriers are less effective at lower frequencies and more effective at higher ones. Some evidence suggests that changes in frequencies are sometimes perceived as changes in noise levels, even though the total A-weighted noise levels do not change significantly.

Sound Propagation

From the source to the receiver noise changes both in level and frequency spectrum. The most obvious is the decrease in noise as the distance from the source increases. The manner in which noise reduces with distance depends on the following important factors:

Geometric spreading from point and line sources

Sound from a small, localized source, approximating a point source, radiates uniformly outward as it travels away from the source in a spherical pattern. For a point source the energy per unit area is inversely proportional to the square of the distance. The sound level attenuates or drops off at a rate of 6 dBA for each doubling of the distance. However, highway traffic noise is not a single, stationary point source of sound. The movement of the vehicles makes the sound appear to emanate from a line rather than a point when viewed over some time interval.

This results in cylindrical spreading rather than spherical spreading of a point source. Since the change in surface area of a cylinder only increases by two times for each doubling of the radius instead of the four times associated with spheres, the change in sound level is 3 dBA per doubling of distance.

Ground absorption

Most often, the noise path between the highway and the observer is very close to the ground. Noise attenuation from ground absorption and reflective wave canceling adds to the attenuation due to geometric spreading. The amount of excess ground attenuation depends on the height of the noise path and the characteristics of the intervening ground or site. This ground attenuation may vary from 0 to 10 dBA per doubling of distance.

Atmospheric effects and refraction

Research by Caltrans and others has shown that atmospheric conditions can have a profound effect on noise levels within 200 feet (60m) from a highway. Wind has shown to be the single most important meteorological factor within approximately 500 feet (150m) while vertical air temperature gradients are more important over longer distances. Other factors such as air temperature and humidity, and turbulence, also have significant effects. Normally, air temperature decreases with height above the ground. This is called the normal lapse rate, which for dry air is 1 degree C per 100m. Since the speed of sound decreases as air temperature decreases, the resulting temperature gradient creates a sound velocity gradient with height. The result is a decrease in noise. Under certain stable atmospheric conditions, however, temperature profiles are inverted. This inversion results in speeds of sound that temporarily increase with altitude resulting in an increase in noise. Noise trapped within an elevated inversion layer may be carried over long distances.

Shielding, noise barriers, diffraction and reflection.

For a vegetative strip to have a noticeable effect on noise levels it must be dense and wide. A stand of trees with a height that extends at least 16 feet (5m) above the line of sight between source and receiver, must be at least 100 feet (30m) wide and dense enough to completely obstruct a visual path to the source to attenuate traffic noise by 5 dBA. Ordinary landscaping along a highway accounts for less than 1 dBA reduction. The first row of buildings, covering at least 40% of the area, will reduce noise levels in the second row by about 3 dBA. Successive rows will reduce noise 1.5 dBA. When a noise barrier is inserted between a noise source and receiver, the direct noise path along the line of sight between the two is interrupted. Some of the acoustical energy will be transmitted through the barrier and continue to the source at a reduced level. The amount of this reduction depends on the material's mass and rigidity and is called the transmission loss. For instance if 1 percent of the noise energy striking the barrier is transmitted,

$$TL = 10Log_{10} (100/1) = 20 \text{ dBA}.$$

Most noise barriers have TLs of 30 dBA or more. That means that only 0.1 percent of the noise energy is transmitted. The remaining direct noise is either partially or entirely absorbed by the noise barrier material or reflected back toward the source and beyond. Ignoring the

difference in path lengths between the direct and reflected noise, the maximum expected increase in noise will be 3 dBA. Sound waves are also diffracted or bent by the sound wall creating a shadow zone behind the barrier. Barriers are more effective in attenuating higher frequencies than lower frequencies. The greater the angle of diffraction, the greater the noise attenuation.

Human Reaction to Noise

Rock music may be pleasant to some people while for others it may be annoying, constitute a health hazard and disrupt activities. Exposure to very high noise levels can damage hearing. Intermittent truck peak noise levels are more objectionable than the continuous level of fan noise. Humans have better hearing sensitivity in the high frequencies. People tend to compare an intruding noise with the existing background noise. If the new noise is readily identifiable or considerably louder than the ambient, it usually becomes objectionable. An aircraft flying over a residential area is an example. An automobile horn at 2 AM is more disturbing than at 5 PM.

Human Response to Change in Noise Levels

Under controlled conditions the trained healthy human ear is able to discern changes in sound levels of 1 dBA, when exposed to steady, single frequency (pure tone) signals in the mid-frequency range. A 3 dBA change is considered barely perceptible, a 5 dBA change is readily noticeable, and a 10 dBA increase is considered twice as loud.

Noise Descriptors

There are dozens of descriptors and scales which have been devised over the years to quantify community noise, aircraft fly-overs, traffic noise, industrial noise, speech interference, etc. Some of the most commonly used descriptors are:

L_{max} (Maximum Noise Level). The highest instantaneous noise level during a specified time period.

L_x (A Statistical Descriptor). The noise level exceeded X percent of a specified time period. The value is commonly 10. Values of L50 and L90 are also used.

Leq (Equivalent Noise Level. Used by Caltrans and FHWA to address the worst hour). The equivalent steady state noise level in a stated period of time that would contain the same acoustic energy as the time varying noise level during the same period.

L_{dn} (Day-Night Noise Level. Used commonly for describing community noise). A 24-hour Leq with a 'penalty' of 10 dBA added during the night hours (2200 hrs – 0700 hrs). The penalty is added because this time is normally sleeping time.

CNEL (Community Noise Equivalent Level. A common community noise descriptor; also used for airport use). Same as Ldn with an additional penalty of 4.77 dBA (or 10Log3) for the hours 1900 – 2200 hrs, usually reserved for relaxation, TV, reading and conversation.

SEL (Single Event Level. Used mainly for aircraft noise, it enables comparing noise created by a loud, but fast overflight, with that of a quieter, but slow overflight). The acoustical energy during a single noise event, such as aircraft overflight, compressed into a period of one second, expressed in decibels.

Noise levels can be converted from one descriptor to another. As a rule of thumb, L_{dn} is approximately (within 2 dBA) equal to the highest hourly L_{eq} noise level.

Negative Effects on Humans

A person exposed to high noise levels can suffer hearing damage. The damage may be gradual or traumatic. Sustained exposure to moderately high noise levels over a period of time can cause gradual hearing loss. It starts out as a temporary hearing loss, such as immediately after a loud rock concert. The hearing usually restores itself within a few hours after exposure, although not quite to its pre-exposure level. This is also called a temporary threshold shift. Although the permanent deterioration may be negligible, it will become significant after many repetitions of the exposure. At that time, it is labeled permanent hearing damage. The main causes of permanent damage are daily exposure to industrial noise. Transportation noise levels experienced by communities and the general public are normally not high enough to produce hearing damage. Short and sudden exposure to an extremely high noise level, such as a gun shot or explosion at very close range can cause a traumatic hearing loss, which can be permanent. Occupational exposure to noise is controlled by OSHA and is based on a maximum allowable noise exposure level of 90 dBA for 8 hours. For each halving of the exposure time, the maximum noise level is allowed to increase by 5 dBA.

As a rough guide, two people 6 meters (20') apart can carry on a normal conversation, if the background noise level is about 50 dBA. If the background level increases to 60 dBA, the distance between the speakers must decrease to about 3 meters (10'). Noise can create stress and contribute to stress related diseases. In general, higher frequency, pure tone and fluctuating noise tend to be more stressful than lower frequency, broad band and constant noise level.

For a discussion on noise measurements, instrumentation, model calibration, construction noise levels, measurement locations, special studies, documentation, meteorology, classroom noise measurements, frequency analysis and quality assurance, refer to the publication 'Technical Noise Supplement' (TeNS), October 1998 by Caltrans.

Study Methods and Procedures

Existing and reasonably expected future activities on all lands that may be affected by noise from the highway must be identified. Existing activities, developed lands and undeveloped lands for which development is planned, designed and programmed, which may be affected by noise from the highway are analyzed. Development is considered planned, designed and programmed, if a noise sensitive land use (subdivision, residences, schools, churches, hospitals, libraries) has received final development approval (generally the issuance of a building permit) from the local agency with jurisdiction.

Glossary

Automobile - Vehicles with two axles and four wheels, generally weighing less than 4500 kg (10,000 pounds) gross weight, including passenger cars, vans and pick-ups.

Bel - A unit used to express loudness, named after Alexander Graham Bell.

dBA - The sound pressure level in decibels measured with a sound level meter having a frequency-weighted network corresponding to the A-Scale used as a standard by the American National Standards Institute (ANSI). The A-Scale tends to suppress lower frequency sounds below 1000 Hertz (Hz) and higher frequencies above 4000 Hz. This correlates well with human hearing response.

Decibel (dB) - One-tenth of a Bel. A unit of measure on a logarithmic scale which denotes the ratio between an air pressure level caused by a given sound and a standard pressure level, usually 0.0002 dynes per square-centimeter.

Existing Noise Levels - The noise resulting from the natural and mechanical sources and human activity, considered to be usually present in a particular area.

Frequency - The number of times the complete wave form (cycle) of an airborne sound pressure level oscillates during one second, referred to as cycles per second or Hertz (Hz).

Heavy Duty Truck (HDT) - Vehicles with three or more axles, generally weighing over 12,000 kg gross weight, including tractor-trailers and concrete-transit mixers. Noise centroid height: 2.4m.

Leq (Equivalent Average Level) - A descriptor of sound. It is the equivalent steady-state sound level which in a stated period of time contains the same acoustic energy as the real fluctuating sound levels during the same period, usually one hour, and expressed as Leq(h).

Loudness - The perceived magnitude of an auditory sensations, that in terms of sound, may be placed on a graduated scale extending from soft to loud. Loudness depends primarily upon the sound intensity of the stimulus, but also depends upon the frequency and wave form of the stimulus. At levels above 40 dB, a 10 dB increase is subjectively judged by the human ear as equal to a doubling of the original loudness.

Medium Duty Truck (MDT) - Vehicles with two axles and six wheels, generally weighing more than 4500 kg, but less than 12,000 kg (26,500 pounds) gross weight, including large delivery trucks, vans and buses. Centroid height: 0.7m.

Meter - The basic unit of measurement in the metric system.

To convert feet to meters, multiply feet by 0.3048

To convert meters to feet, divide meters by 0.304

Noise - Noise is defined as unwanted sound.

Noise Level - Resultant level of measured frequency weighted sound levels or resultant of computer calculations.

Receptor - A location for noise measurements or a site to compute noise levels.

Sound - The auditory sensation produced when the organs of hearing transform mechanical energy transmitted by airborne pressure variations (sound waves) into an electric signal which is transmitted via nerve pathways to the brain. Not all sound waves cause auditory sensations, for example, ultrasound frequencies.

Project Cost estimate

Common Indoor and Outdoor Noise Levels

Outdoor		dBA	Indoor	•
22 Caliber Rifle	0.6m	140	Child's Toy Cap Pistol	0.3m
Threshold of Pain		130	Symphony Orchestra (loud passa	age)
Pile Driver (Average)	15m	120		
Chain Saw Emergency Vehicle	0.6m 8m	110	Rock Band	
Jet Flyover Street Jackhammer Leaf Blower	305m 8m	100	Power Hand Saw	1.0m
BART Train Gas Lawn Mower	1.5m 1.0m	90	Power Hand Sander Shop Vacuum Cleaner	1.0m 1.5m
Diesel Truck Busy Restaurant	15m		Food Blender Rug Shampooer Garbage Disposal	1.0m 1.5m 1.0m
Gas Lawn Mower	15m	80	Vacuum Cleaner Shouting	1.5m 1.0m
FHWA/Caltrans NAC		70 	Normal Speech	1.0m
Average Residential Neighborhood (Daytime)	60	Large Business Office	
Average Residential Neighborhood (Nighttim	ne)	50	Dishwasher next Room	
		40		
Soft Whisper	1.0m	3 0	Library Bedroom at Night	
Rustling of Leaves		20	Concert Hall	
Mosquito	1.0m	10	Broadcasting-Recording Studio	
Treshold of Hearing		0

Description of Activities Categories

- A Lands of which serenity and quiet are of extraordinary significance and serve an important public need, and where the preservation of those qualities is essential if the area is to continue to serve its intended purpose.
- **B** Picnic areas, recreation areas, playgrounds, active sports areas, parks, residences, motels, hotels, schools, churches, libraries, and hospitals.
- C Developed lands, properties, or activities not included in Categories A or B above.
- D Undeveloped lands.
- E Residences, motels, hotels, public meeting rooms, schools, churches, libraries, hospitals, and auditoriums.

Assumptions and Limiting Conditions

- 1. This estimate was completed using information provided by Tony Wong of Design East Alameda I.
- 2. This estimate was completed without the benefit of a hazardous waste report.
- 3. Potholing was completed using general information provided by utility coordinator for potholing in the District.

Evaluation Prep	ared By:	LYNN WHITE		/ /
Right of Way:	Name	La Whitz	Date	3/19/01
Railroad:	Name	Seta Caza	Date	4/19/01

		Recommended for Ap	proval:	1 1

Right of Way Capital Cost Coordinator

I have personally reviewed this Right of Way Data Sheet and all supporting information. It is my opinion that the probable Highest and Best Use, estimated values, escalation rates, and assumptions are reasonable and proper subject to the limiting conditions set forth, and find this Data Sheet complete and current.

Chief, R/W Appraisal Services

Project Deliverables and Responsible Unit

For detailed schedule and resources estimates refer to attached District 4 workplan Attachment B

Deliverable	# of Plan Sheets	Responsible Unit	WBS Activity Codes
Title Sheet	1	NRDesign	230
Typical Sections	1	NRDesign	230
Layouts	14	NRDesign	185, 230
Construction Details	5	NRDesign	230
Drainage Plans	6	NRDesign	230
Drainage Profiles	4	NRDesign	230
Drainage Details	- 2	NRDesign	230
Drainage Q Sheets	2	NRDesign	230
Utility Plans	4	NRDesign	230
Stage Construction	4	NRDesign	230
Construction Signing	2	NRDesign	230
Pavement Delineation	. 0	NRDesign	230
Quantities	2	NRDesign	230
Electrical	2	NREngrSvs	230
Signing	1	NRDesign	230
Specs & Estimate		NROE,NRDesign	230, 255, 260, 265
Design Support to Const.		NRDesign	270, 285
Project Management		NRDesign	100
Landscape		NRLandscape	230
Total	50
